

ABSTRACT OF THE DISCLOSURE

The invention relates to management of data packets and buffers comprising segments of data packets in a mobile communication system (1). Information associated with data packet segments is analyzed by a Base Station System (BSS) (100) housing a data buffer (120). Based on this information analysis, the BSS (100) can identify those segments ($P(\text{FIRST}) - P(\text{LAST})$) in the buffer (120) that constitutes a complete data packet. Once identified, the segments can be discarded from the buffer (120). The information can include size information ($S(k), S(k+1)$), whereby the analysis comprises pairwise comparing the size ($S(k)$) of a current segment ($P(k)$) with the size ($S(k+1)$) of a next consecutive segment ($P(k+1)$). This size comparison enables identification of a first segment ($P(\text{FIRST})$) and a last segment ($P(\text{LAST})$) of the complete data packet. The information could also, or alternatively, include a notification provided in the header of the segment. This notification identifies the associated segment as the first or last segment of the data packet or an intermediate segment.
